Chapter 1

Introduction

GAPT is a general architecture for proof theory implemented in Scala. The focus of GAPT are proof transformations (in contrast to proof assistants, whose focus is proof formalization, and automated deduction systems, whose focus is proof search). GAPT can be used from an interactive shell that provides access to the functionality in the system in a way that is inspired by computer algebra systems: the basic objects are formulas and (different kinds of) proofs which can be modified by calling GAPT commands from the command line. In addition, there is a graphical user interface that allows the user to view (and to a certain extent modify) proofs in a flexible and visually appealing way.

The current functionality of GAPT includes data structures for formulas, sequents, resolution proofs, sequent calculus proofs, expansion tree proofs and algorithms for e.g. unification, proof Skolemization, cut-elimination, cut elimination by resolution [4], cut-introduction [11], etc. It contains a built-in superposition prover, an inductive theorem prover, as well as interfaces to numerous external theorem provers and solvers.

This user manual is an introduction to the usage of GAPT, mostly based on examples. We recommend that you try out these examples in your installation of GAPT while reading this manual.
Chapter 2

Download and execution

There are three ways you can obtain GAPT:

1. **The recommended way:** You can download a package of the current version of GAPT at [https://logic.at/gapt/](https://logic.at/gapt/). After extracting the tar.gz-file, you will find a shell script `gapt.sh`.
   
   Running this script will start the command line interface of GAPT:
   ```
   ./gapt.sh
   ```

2. If you are adventurous, you can also download the current development version from github:
   ```
   git clone https://github.com/gapt/gapt
   cd gapt
   sbt console
   ```

3. If you like GAPT and want to use it as a library in your Scala project, it is available as a Maven artifact on Maven Central. All you need to do is add the following line to your `build.sbt`:
   ```
   libraryDependencies += "at.logic.gapt" %% "gapt" % "2.16.0"
   ```

The command line interface of GAPT is an interactive Scala shell. This means that all functionality of Scala is available to you. In particular it is easy to write Scala scripts that use the functionality of GAPT.

You don’t need to know anything about Scala to try out the examples in this manual, but if you do want to learn more about Scala we recommend the book “Programming in Scala” [15].

Interactions with the Scala shell are typeset in the following way:

```gapt>
println("Hello, world!")
Hello, world!
```

Here, `println("Hello, world!")` is the user input, and `Hello, world!` is the output from the Scala shell.

If you want to consult the in-depth API documentation of a function, you can use the `help` command:
2.1 Required and optional software

To run GAPT you need to have Java 8 (or higher) installed.

GAPT contains interfaces to the following automated reasoning systems. Installing them is optional.

If GAPT does not find the executables in the path, the functionality of these systems will not be available.

- Prover9 (http://www.cs.unm.edu/~mccune/mace4/download/) - make sure the commands prover9 and prooftrans are available.
- E theorem prover (http://eprover.org/)
- Vampire 4.0 (https://vprover.github.io/)
- SPASS (http://www.spass-prover.org/)
- LeanCoP (http://leancop.de/)
- Metis (http://www.gilith.com/software/metis/)
- iProver (http://www.cs.man.ac.uk/~korovink/iprover/, requires a development version as of September 11, 2017)
- VeriT (http://www.verit-solver.org/)
- Z3 (https://github.com/Z3Prover/z3)
- SMTInterpol (https://ultimate.informatik.uni-freiburg.de/smtinterpol/)
- MiniSAT (http://minisat.se/)
- Glucose (http://www.labri.fr/perso/lisimon/glucose/)
- PicoSAT (http://fmv.jku.at/picosat/)
- Sat4J (http://sat4j.org/)

- CVC4 (https://cvc4.github.io/)
- TIP tools (https://github.com/tip-org/tools)
Chapter 3

Data structures

3.1 Expressions and formulas

Formulas, terms, and all other expressions are represented as terms in a polymorphic simply-typed lambda calculus. GAPT’s lambda calculus also supports multiple base sorts and inductive types, see Appendix A for a complete definition. For example, the formula $\forall x P(x,y)$ is encoded as the term $\forall x (P(x)) y$). This term has the type $o$, which is the type of Boolean values. The variable $x$ in this term has the type $i$, which is the default type for first-order variables.

There are two ways of entering expressions: you can parse them or construct them manually.

3.1.1 Formula parsing

Here is an example of parsing a first-order formula:

```
gapt> val F = fof"!x (P(x,f(x)) -> ?y P(x,y))"
val F: gapt.expr.formula.fol.FOLFormula = \forall x (P(x, f(x)) \rightarrow \exists y P(x, y))
```

Every kind of expression that GAPT supports can be parsed by writing `<prefix>`<string>`. The prefix indicates the Scala type of the expression. The following prefixes are available:

- `ty` type
- `le` lambda expression
- `hof` higher-order formula
- `hoa` higher-order atom
- `hov` higher-order variable
- `hoc` higher-order constant
- `foe` first-order expression
- `fof` first-order formula
- `fot` first-order term
- `foa` first-order atom
- `fov` first-order variable
- `foc` first-order constant
This parser supports Scala string interpolation. For example, you can do:

```
gapt> val t = fot"f(f(x))"
gapt.expr.formula.fol.FOLTerm = f(f(x))
```

```
gapt> val G = fof"!x (P(x, f(t)) -> ?y P(x, y))"
val G: gapt.expr.formula.fol.FOLFormula = ∀x (P(x, f(f(x))) → ∃y P(x, y))
```

Note that Scala string interpolation is different from (capture-avoiding) substitution.

The input language has full type inference, and the formula prefixes make sure that the expression is of type $o$ (Boolean). If no particular type is required, we default to $ι$:

```
gapt> hof"!x?y!z x(z) = y(y(z))"
val res0: gapt.expr.formula.Formula = ∀x ∃y ∀z (x(z): i) = y(y(z): i)
```

So far we have only used the ASCII-safe part of the syntax, however Unicode input is of course supported as well—you can paste any of the output right back in:

```
gapt> hof"∀x ∃y ∀z x(z) = y(y(z))"
val res1: gapt.expr.formula.Formula = ∀x ∃y ∀z (x(z): i) = y(y(z): i)
```

Here is a summary of the available syntax (there are usually multiple variants of each construct, these are separated by commas here):

- $x$1, uvw variables (need to start with u-z or U-Z, or be bound)
- c, theorem constants
- $f(x,c), f(x)(c), f x c$ function application
- $λx f(x), ^x f(x)$ lambda abstraction
- $!x p(x), !(x:i) p(x), ∀x p(x)$ universal quantification
- $?x p(x), ?(x:i) p(x), ∃x p(x)$ existential quantification
- $¬p, p → q$ negation
- $p \land q, p \lor q$ conjunction
- $p \mid q, p \lor q$ disjunction
- $p \rightarrow q, p \rightarrow q$ implication
- $p ↔ q$ equivalence (this is the same as $p \rightarrow q \land q \rightarrow p$)
- $p = q, p = q = r$ equality
- $p \neq q$ disequality
- $p < q, \leq r \geq s$ various infix relations
- $a*b/c + d - e$ infix operators
- $f: i>i>o$ type annotation

### 3.1.2 Constructing formulas manually

Every kind of expression that exists in GAPT can be constructed manually. For instance, you can define variables and constants like this:

```
gapt> val x = FOLVar("x")
val x: gapt.expr.formula.fol.FOLVar = x
```
gapt> val P = Const("P", Ti ->: To)
val P: gapt.expr.Const = P:i>o

Var and Const require you to supply types, whereas FOLVar and FOLConst automatically have type \( \iota \). Terms and atomic formulas are constructed similarly:

```gapt
val x = FOLVar("x")
val x: gapt.expr.formula.fol.FOLVar = x

gapt> val fx = FOLFunction("f",x)
val fx: gapt.expr.formula.fol.FOLTerm = f(x)

gapt> val Pfx = FOLAtom("P", fx)
val Pfx: gapt.expr.formula.fol.FOLAtom = P(f(x)): o
```

On the formulas themselves, there are operators for the various Boolean connectives:

```
-A 
A & B  A \land B
A | B  A \lor B
A --> B  A \rightarrow B
A <-> B  A \leftrightarrow B
```

```gapt
val A = FOLAtom("A")
val A: gapt.expr.formula.fol.FOLAtom = A:o

gapt> val B = FOLAtom("B")
val B: gapt.expr.formula.fol.FOLAtom = B:o

gapt> val C = FOLAtom("C")
val C: gapt.expr.formula.fol.FOLAtom = C:o

gapt> (A & B) --> C
val res2: gapt.expr.formula.fol.FOLFormula = A \land B \rightarrow C
```

### 3.1.3 Predefined formulas

A collection of formula sequences can be found in the file examples/FormulaSequences.scala. You can generate instances of these formula sequences by entering for example:

```gapt
val f = BussTautology( 5 )
val f: gapt.proofs.HOLSequent =
((c_1 \lor d_1) \land (c_2 \lor d_2) \land (c_3 \lor d_3) \land (c_4 \lor d_4) \rightarrow c_5) \lor
((c_1 \lor d_1) \land (c_2 \lor d_2) \land (c_3 \lor d_3) \land (c_4 \lor d_4) \rightarrow d_5),
((c_1 \lor d_1) \land (c_2 \lor d_2) \land (c_3 \lor d_3) \lor (c_4 \lor d_4) \rightarrow c_4),
((c_1 \lor d_1) \land (c_2 \lor d_2) \land (c_3 \lor d_3) \lor (c_4 \lor d_4) \rightarrow d_4),
((c_1 \lor d_1) \land (c_2 \lor d_2) \rightarrow c_3) \lor ((c_1 \lor d_1) \land (c_2 \lor d_2) \rightarrow d_3),
(c_1 \lor d_1 \rightarrow c_2) \lor (c_1 \lor d_1 \rightarrow d_2),
c_1 \lor d_1
```
3.2 Sequents

Sequents are an important data structure in GAPT. A sequent is a pair of lists:

\[ A_1, ..., A_m \vdash B_1, ..., B_n \]

The list to the left of the sequent symbol \( \vdash \) is called the antecedent, the one on the right the succedent. Usually, but not always, the elements of the sequences are going to be formulas.

In GAPT, you can create sequents by supplying an antecedent and a succedent:

```gapt
gapt> val S1 = Sequent()
gapt> val S2 = Sequent(List(1,2), List(3,4))
gapt> val S3 = Sequent(List(foa"A", foa"B"), List(foa"C", foa"D"))
```

Sequents of formulas can also be parsed:

```gapt
gapt> hos"P a, a = b :- P b"
```

The following prefixes are available (a clause is a sequent of atoms):

- **hos** higher-order (formula) sequent
- **hcl** higher-order clause
- **fos** first-order (formula) sequent
- **fcl** first-order clause

Sequents have append operations for both the antecedent and the succedent. In the antecedent, elements are appended to the left, in the succedent, to the right:

```gapt
gapt> val S1 = fcl"B :- C"
gapt> val S2 = foa"A" :+: S1
```

```gapt
gapt> val S3 = S2 :+: foa"D"
```

```gapt
val res1: gapt.proofs.Sequent[gapt.expr.formula.fol.FOLAtom] = A, B \vdash C, D
```
You can retrieve elements from a sequent either by accessing the antecedent or succedent directly...

```
gapt> val S = fc1"A, B :- C, D"
gapt> val b = S.antecedent(1)
gapt> val c = S.succedent(0)
```

... or by using the `SequentIndex` class:

```
gapt> val i = Ant(0)
gapt> val j = Suc(1)
gapt> val a = S(i)
gapt> val d = S(j)
```

3.3 Proofs

3.3.1 The sequent calculus LK

GAPT contains an implementation of Gentzen's sequent calculus LK. The inference rules are defined in Appendix B.1.

There are various possibilities for entering proofs into the system. The most basic one is a direct top-down proof-construction using the constructors of the inference rules. We discuss this possibility in this section. For entering bigger proofs, it is more convenient to use the “gaptic” tactics language which is discussed in Section 3.5.

**Note:** Many correctness properties of LK proofs are purely syntactic and are checked at construction time. For instance, it is not possible to construct a proof that violates the eigenvariable condition of strong quantifier rules. However, some rules require additional assumptions to be correct. For example, the induction rule is only correct under the assumption that the cases used in the rule correspond precisely to the inductive type’s constructors. Assumptions of this kind are collected in a Context, see Section 3.4. Since top-down proof construction does not take contexts into account, it can result in proofs violating these assumptions. You can ensure that a proof you have constructed conforms to a context ctx by using the check method on ctx.

We start with the axioms:
These are joined by an \(\land\):r-inference.

To finish the proof it remains to apply two \(\to\):r-inferences:

You can now view this proof by typing:

There are also several macro rules that make proof construction more convenient. For instance:

Here, the \(\land\):l macro rule automatically adds \(B\) by weakening before performing the \(\land\):l inference.
which are generated in the above style. Have a look at this code for more complicated proof con-
structions. You can generate instances of these proof sequences by entering, e.g.,

```
gapt> val p = SumExampleProof( 5 )
val p: gapt.proofs.lk.LKProof =
[p25] ∀x ∀y (P(s(x), y) → P(x, s(y))), P(s(s(s(s(0)))), 0) ⊢ P(0, s(s(s(s(0)))))) (ContractionLeftRule(p24, Ant(0), Ant(1)))
[p24] ∀x ∀y (P(s(x), y) → P(x, s(y))), ∀x ∀y (P(s(x), y) → P(x, s(y))),
P(s(s(s(s(0)))), 0)
∈
P(0, s(s(s(s(0)))))) (ForallLeftRule(p23, Ant(0), ∀y (P(s(x), y) → P(x, s(y))), 0, x))
[p23] ∀y (P(s(0), y) → P(0, s(y))),
P(s(s(s(s(0)))), y)
∈
P(0, s(s(s(s(0)))))) (ImpLeftRule(p20, Suc(0), p21, Ant(0)))
[p21] P(0, s(s(s(s(0)))))) ⊢ P(0, s(s(s(s(0)))))) (LogicalAxiom(...
```

3.3.2  Natural Deduction ND

GAPT contains an implementation of Gentzen’s natural deduction calculus ND. The ND-calculus
works on sequents which contain exactly one formula in the succedent. The formulas in the an-
tecedent are the currently open assumptions. This is captured in the NDSequent class. The inference
rules are defined in Appendix B.2. To use the natural deduction inference rules you need to qualify
the rule names with “nd.”.

We show that from \( P \land Q \rightarrow R \) and \( P \) follows \( Q \rightarrow R \). We start with the axioms:

```
gapt> val p1 = nd.LogicalAxiom( fof"P" )
val p1: gapt.proofs.nd.LogicalAxiom =
[p1] P ⊢ P (LogicalAxiom(P:o))

gapt> val p2 = nd.LogicalAxiom( fof"Q" )
val p2: gapt.proofs.nd.LogicalAxiom =
[p1] Q ⊢ Q (LogicalAxiom(Q:o))

gapt> val p3 = nd.LogicalAxiom( fof"P & Q -> R" )
val p3: gapt.proofs.nd.LogicalAxiom =
[p1] P \land Q \rightarrow R ⊢ P \land Q \rightarrow R (LogicalAxiom(P \land Q \rightarrow R))
```

\( P \) and \( Q \) are joined by an \( \land \)-introduction inference.

```
gapt> val p4 = nd.AndIntroRule( p1, p2 )
```
Next, we apply a $\rightarrow$-elimination inference on $P \land Q \rightarrow R$ and $P \land Q$ to arrive at $R$.

```
gapt> val p5 = nd.ImpElimRule( p3, p4 )
val p5: gapt.proofs.nd.ImpElimRule =
[p5] P \land Q \rightarrow R, P, Q \vdash R (ImpElimRule(p1, p4))
[p4] P, Q \vdash P \land Q (AndIntroRule(p2, p3))
[p3] Q \vdash Q (LogicalAxiom(Q:o))
[p2] P \vdash P (LogicalAxiom(P:o))
[p1] P \land Q \rightarrow R \vdash P \land Q \rightarrow R (LogicalAxiom(P \land Q \rightarrow R))
```

Finally, by using an $\rightarrow$-introduction inference on $Q$, we arrive at the desired sequent.

```
gapt> val p6 = nd.ImpIntroRule( p5, Ant( 2 ) )
val p6: gapt.proofs.nd.ImpIntroRule =
[p6] P \land Q \rightarrow R, P \vdash Q \rightarrow R (ImpIntroRule(p5, Ant(2)))
[p5] P \land Q \rightarrow R, P, Q \vdash R (ImpElimRule(p1, p4))
[p4] P, Q \vdash P \land Q (AndIntroRule(p2, p3))
[p3] Q \vdash Q (LogicalAxiom(Q:o))
[p2] P \vdash P (LogicalAxiom(P:o))
[p1] P \land Q \rightarrow R \vdash P \land Q \rightarrow R (LogicalAxiom(P \land Q \rightarrow R))
```

You can now view this proof by typing:

```
gapt> prooftool( p6 )
```

Also for ND there are several convenience constructors which simplify proof construction, which can be found in the API documentation.

### 3.4 Contexts

The Context class captures the notion of a logical signature and background theory.

A context may contain declarations of:

- sorts and inductive types
- constants with previously declared types
- definitions
- Skolem functions
- Proof links
Various data structures and algorithms in GAPT require the presence of an implicit value of type Context in order to work. For example, the expression parser uses type and constant declarations to decide how to parse identifiers. Another example is the eliminateDefinitions proof transformation: you may manually pass it a list of definitions to eliminate from a proof, or have it automatically eliminate all definitions in the current context. Some gaptic tactics (see Section 3.5) also require a context.

The typical way to declare a context is by starting with a default value and adding elements to it. The Context.default object contains only the sort o (truth values) and the fundamental logical symbols. An example for a context is:

```scala
object ContextExample {
  implicit val ctx = MutableContext.default()
  ctx += InductiveType("Nat", hoc" 0: Nat", hoc" s: Nat > Nat") //Adding a type declaration
  ctx += hoc" ' + ': Nat>Nat>Nat" //Adding a constant declaration
  ctx += "plus_zero" -> hoc" :- \forall n (n + 0 = n)" //Adding a theory axiom
  ctx += "1" -> le" s 0" //Adding a definition
  ctx += hof" leq x y = (\exists z x + z = y)" //Adding a definition as an equation
}
```

It is important that you declare the context as implicit, so that it can be found automatically by the functions requiring it.

Once you have constructed a context, you can check whether an expression, formula, sequent, or proof conforms to it by using its check method.

### 3.5 The tactics language gaptic

GAPT contains a simple tactics language called gaptic for the construction of LK proofs. In contrast to the top-down construction presented in Section 3.3, gaptic allows a comfortable bottom-up development of proofs, similar to popular proof assistants such as Coq, Isabelle, etc.

#### 3.5.1 Overview

Gaptic can not be (easily) used in the interactive Scala shell, as it requires multi-line input. Gaptic scripts are usually developed as external files:

```scala
import gapt.expr._
import gapt.proofs.context.update.Sort
import gapt.proofs.Sequent
import gapt.proofs.gaptic._

object example extends TacticsProof {
  ctx += Sort("i")
  ctx += hoc"P: i>o"
  ctx += hoc"Q: i>o"
}
Gaptic proofs start with a context declaration. For more information on contexts, see Section 3.4.

**Note:** Unlike top-down proof construction, proofs constructed with Gaptic are automatically correct with respect to the current context.

Each proof is then assigned to a Scala variable. The function `Lemma(labelledSequent) { tactics... }` constructs a proof using the gaptic language. The first argument of `Lemma` is the labelled end sequent, i.e. the sequent you want to prove in which each formula has a string label. The second argument consists of a list of statements, called tactics, separated by line breaks.

At the moment, there are two ways to execute gaptic scripts:

1. From the Scala shell, using the :load command. This command evaluates the Scala file, but not the code inside the object declaration. So we have to explicitly evaluate the proof ourselves.

   ```scala
   gapt> :load example.scala
   gapt> example.lemma
   ```

2. As a separate SBT project, see https://github.com/gapt/gaptic-example for a template project. This approach has the advantage that SBT can automatically run your script whenever you save it:

   ```scala
   > runMain example
   [info] Running example
   [success] Total time: 1 s, completed Apr 5, 2016 11:16:32 AM
   ```

   1. Waiting for source changes... (press enter to interrupt)

Let us use gaptic to input a very simple proof. Our first try might be the following (we now omit the boilerplate for brevity):

```scala
val lemmaEx = Lemma(Sequent(Seq("a" -> fof"P a"), Seq("b" -> fof"\forall x (P x \rightarrow Q x)"), Seq("c" -> fof"Q a")) { allL(fof"a") })
```
As seen above, the currently open goals are shown when the proof is not yet completed. Upon completion of the proof, the value of \texttt{lemmaEx} is the resulting proof:

```
val lemmaEx =
  Lemma(Sequent(
    Seq("a" -> fof"P a", "b" -> fof"!x (P x -> Q x)"),
    Seq("c" -> fof"Q a"))) {
  allL(fot"a")
  impL
  trivial
  trivial
}
```

Most tactics can be called with or without a label argument. If a tactic is called with a label, it will be applied to that specific formula, if possible. Otherwise, the system will attempt to determine a target formula on its own. If there is either no applicable formula or more than one, the tactic will fail.

### 3.5.2 Basic tactics

We now give a description of a few basic tactics, you can find the full list in the API documentation:

```
gapt> help(gapt.proofs.gaptic.TacticCommands)
```

The forget tactic corresponds to weakening rules in LK. It accepts a list of labels and removes the formulas with those labels from the current subgoal:

```
val lemmaEx =
  Lemma(Sequent(
    Seq("a" -> fof"P a", "b" -> fof"!x (P x -> Q x)"),
    Seq("c" -> fof"Q a"))) {
  forget("b")
}
```

```
gapt.proofs.gaptic.QedFailureException: Proof not completed. There are still 1 open sub goals:
```
The tactics axiomLog, axiomRef1, axiomBot and axiomTop cover the logical, reflexivity, bottom and top axioms, respectively. The trivial tactic automatically selects the applicable axiom. Also, any weakening rules required to reach an actual axiom sequent are automatically applied.

The following example shows the use of the trivial tactic to end the proof by a logical axiom:

```scala
val axiomEx =
  Lemma(Sequent(Nil,
    Seq("D" -> fof"?x (P x -> !y P y)"))) {
    exR(fov"c")
    impR
    allR
    exR(fov"y")
    impR
    allR
    trivial
  }
```

The tactic eql covers the left and right equality rules. Its first argument is the label of an equality in the antecedent. The second argument is the label of the formula to apply the rule to. Furthermore, you may specify whether to apply the equation from left to right or vice versa. Also, a target formula can be specified, if not all occurrences need to be replaced (in either direction). If neither direction nor a target formula is specified, the tactic will only work if the direction is unambiguous.

```scala
val eqEx = Lemma(Sequent(
  Seq("c" -> fof"P(y) & Q(y)",
    "eq1" -> fof"u = (v:i)",
    "eq2" -> fof"y = (x:i)",
    "a" -> fof"P(u) -> Q(u)"),
  Seq("b" -> fof"P(x) & Q(x)"))) {
  eql("eq1", "a").yielding(fof"P(v) -> Q(v)")
  eql("eq1", "a").yielding(fof"P(v) -> Q(u)")
  eql("eq2", "b").fromRightToLeft
  trivial
}
```

The tactics for the weak quantifiers are allL and exR. They are called with the list of terms to instantiate the quantified formula with. One call of allL or exR can instantiate any number of quantifiers in a formula. The tactics for the strong quantifiers are allR and exL. They are optionally...
called with the variable that should be used as an eigenvariable. If no eigenvariable is provided, a fresh variable will automatically be generated. The weak quantifier formulas are kept in the sequent after instantiations while the strong quantifier formulas are automatically removed.

```plaintext
val quantEx = Lemma(Sequent(
    Seq("D -> fof("(!x (P(x) & (?y -P(y))))"),
    Nil)) { allL(fot"c:i")
    andL
    exL(fov"y_0")
    negL
    allL(fov"y_0")
    andL
    exL(fov"y_1")
    negL
    axiomLog
})
```

The implication, negation, disjunction and conjunction rules are covered by the tactics impL, impR, negL, negR, disL, disR, conL and conR, respectively. They are similar in the sense that they take no arguments apart from an optional label to apply the tactic to.

```plaintext
val propEx = Lemma(Sequent(
    Seq("initAnt" -> fof("A -> B"),
    Seq("initSuc" -> fof("(A & B) | -A")}) {
    orR("initSuc")
    negR("initSuc_1")
    andR("initSuc_0")
    trivial
    impL
    trivial
    trivial
})
```

The cut tactic is used to introduce a cut rule. The first argument is the (unique new) label for the cut formula, the second argument is the cut formula itself. Both arguments are mandatory. In the case where a non-unique label is provided the tactic simply fails.

```plaintext
val cutEx = Lemma(Sequent(
    Seq("A" -> fof("A"),
    Seq("C" -> fof("?x?y ( -x=y & f(x)=f(y) )")}) {
    cut("I1", fof("I(1)"))
    cut("I0", fof("I(0)"))
})
```

gapt.proofs.gaptic.QedFailureException: Proof not completed. There are still 3 open sub goals:
A: A
:-
Using gaptic, we can also create proofs with induction. For example, let us prove that concatenation of lists is associative:

ctx += Sort("i")

// Define the type of lists.
ctx += InductiveType("list",
    hoc"nil: list",
    hoc"cons: i>list>list")

// Declare a constant denoting concatenation.
// We will axiomatize its definition in the end-sequent.
ctx += hoc"/quotesingle.Var+/quotesingle.Var: list>list>list"
ctx += Notation.Infix("+", Precedence.plusMinus)

val catassoc =
    Lemma(
        ("conscat" -> hoc"∀x ∀y ∀z cons(x,y)+z = cons(x,y+z") +:
        ("nilcat" -> hoc"∀x nil+x = x") +:
        Sequent()
        +( "goal" -> hoc"∀x ∀y ∀z x+(y+z) = (x+y)+z")
    )
    { decompose; induction(hov"x: list")
      rewrite.many ltr "nilcat”; refl
      rewrite.many ltr ("conscat", "IHx_0"); refl
    }
4.1 Reductive cut-elimination

The GAPT-system contains an implementation of Gentzen-style reductive cut-elimination. It can be used as follows: first we load a proof \( p \) with cuts:

```gapt
val p = examples.fol1.proof
```

\[
\forall x \forall y (P(x, y) \rightarrow Q(x, y)) \vdash \exists x \exists y (\neg Q(x, y) \rightarrow \neg P(x, y)) \tag{CutRule(p9, Suc(0), p24, Ant(0)))
\]

```gapt
val q = cutNormal( p )
```

\[
\forall x \forall y (\neg P(x, y) \lor Q(x, y)) \vdash \exists x \exists y (\neg Q(x, y) \rightarrow \neg P(x, y)) \tag{ForallLeftRule(p23, Ant(0), \exists y (\neg P(x, y) \lor Q(x, y)), b, x))
\]

and then call the cut-elimination procedure:

```gapt
val q = cutNormal( p )
```

\[
\neg P(b, y) \lor Q(b, y) \vdash \exists x \exists y (\neg Q(x, y) \rightarrow \neg P(x, y)) \tag{ExistsRightRule(p21, Suc(0), \exists y (\neg Q(x, y) \rightarrow \neg P(x, y)), b, x))
\]

\[
\neg P(b, y) \lor Q(b, y) \vdash \exists y (\neg Q(b, y) \rightarrow \neg P(b, y)) \tag{ExistsRightRule(p20, Suc(0), \neg Q(b, y) \rightarrow \neg P(b, y), y, y))
\]

\[
\neg P(b, y) \lor Q(b, y) \vdash \neg Q(b, y) \rightarrow \neg P(b, y) \tag{ContractionRightRule(p19, Suc(1), Suc(0)))
\]

\[
\neg P(b, y) \lor Q(b, y) \vdash \neg Q(b, y) \rightarrow \neg P(b, y), \neg Q(b, y) \rightarrow \neg P(b, y) \tag{OrLeftRule(p14, Ant(0), p18, Ant(0)))
\]

...
4.2 Induction-elimination

Along the lines of Gentzen’s proof of the consistency of Peano arithmetic, GAPT can also eliminate induction inferences in a restricted class of proofs with quantifier-free conclusions.

```
gapt> val p = instanceProof(examples.theories.nat.addcomm.combined(),
  Seq(le"s (s 0 : nat)", le"0 : nat"))
val p: gapt.proofs.lk.LKProof =
[p118] ∀ x ((x:nat) + (0:nat): nat) = x,
∀ x ∀ y x + y = s(y:nat) = s(x + y)
⊢ s(s(0)) = 0 + s(s(0)) (CutRule(p114, Suc(0), p117, Ant(0)))
[p117] ∀ x ∀ y ((x:nat) + (y:nat): nat) = y + x ⊢ s(s(0:nat): nat) + 0 = 0 + s(s(0)) (ForallLeftRule(p116, Ant(0), ∀ y ((x:nat) + (y:nat): nat) = y + x, s(s(0:nat): nat), x :nat))
[p116] ∀ y (s(s(0:nat): nat) + (y:nat): nat) = y + s(s(0)) ⊢ s(s(0)) + 0 = 0 + s(s(0)) (ForallLeftRule(p115, Ant(0), s(s(0:nat): nat) + (y:nat): nat) = y + s(s(0)), 0:nat, y :nat))
[p115] (s(s(0:nat): nat) + 0: nat) = 0 + s(s(0)) ⊢ s(s(0)) + 0 = 0 + s(s(0)) (LogicalAxiom((s(s(0:nat): nat) + 0: nat) = 0 + s(s(0))))
[p114] ∀ x ((x:nat) + (0:nat): nat) = x, ∀ x ∀ y x + y = s(y:nat) = s(x + y)
⊢ ∀ x ∀ y x + y = y + x (CutRule(p3, Suc(0), p113, Ant(...
```

```
gapt> val q = inductionNormalForm(p)(
  nat.ctx)
val q: gapt.proofs.lk.LKProof =
[p16] ∀ x_1 ((x_1:nat) + (0:nat): nat) = x_1,
∀ x_1 ∀ y x_1 + y = s(y:nat) = s(x_1 + y)
⊢ s(s(0)) = 0 + s(s(0)) (ContractionLeftRule(p15, Ant(0), Ant(2)))
[p15] ∀ x_1 ((x_1:nat) + (0:nat): nat) = x_1,
∀ x_1 ∀ y x_1 + y = s(y:nat) = s(x_1 + y),
∀ x_0 x_0 + 0 = x_0
⊢ s(s(0)) = 0 + s(s(0)) (ForallLeftRule(p14, Ant(2), ((x_1:nat) + (0:nat): nat) = x_1, 0:nat, x_1:nat))
[p14] ∀ x_1 ∀ y ((x_1:nat) + (y:nat): nat) = s(x_1 + y),
∀ x_0 x_0 + 0 = x_0,
```

24
\[0 + 0 = 0\]
\[
\vdash s(s(0)) + 0 = 0 + s(s(0)) \quad \text{(ForallLeftRule(p13, Ant(1)), } \forall y ((x_1: \text{nat}) + (y: \text{nat}): \text{nat}) = s(x_1 + y), 0: \text{nat}, x_1: \text{nat})
\]

[p13] \[\forall x_0 ((x_0: \text{nat}) + (0: \text{nat}): \text{nat}) = x_0,
\forall y + s(y: \text{nat}) = s(0 + y),
0 + 0 = 0\]
\[
\vdash s(s(0)) + 0 = 0 + s(s(0)) \quad \text{(ForallLeftRule(p12, Ant(2)), } ((x_0: \text{nat}) + (0: \text{nat}): \text{nat}) = x_0
\]

The resulting proof \(q\) contains only atomic cuts, and we can view its Herbrand sequent by converting to an expansion proof:

\begin{verbatim}
gapt> LKToExpansionProof(q) val res0: gapt.proofs.expansion.ExpansionProof =
\forall x_1 ((x_1: \text{nat}) + (0: \text{nat}): \text{nat}) = x_1
\vdash \forall y ((x_1: \text{nat}) + (s(y: \text{nat}): \text{nat}): \text{nat}) = s(x_1 + y)
\vdash \forall \theta, \theta (\theta + \theta = 0)\]
\vdash \forall s(0): \text{nat}) (s(s(0)) + 0 = s(s(0)))
\vdash \forall x_1 \forall y ((x_1: \text{nat}) + (s(y: \text{nat}): \text{nat}) = s(x_1 + y)
\vdash \forall \theta, \theta (\theta + \theta = 0)\]
\vdash \forall \theta, \theta (\theta + \theta = 0)
\vdash ((s(0): \text{nat}) + \theta: \text{nat}) = 0 + s(s(0))\]
\end{verbatim}

\section{4.3 Skolemization}

Skolemization is the process of introducing Skolem functions for strong quantifiers, and is usually performed during classification of formulas into CNF (clause/conjunctive normal form). The \texttt{structuralCNF} function takes a sequent and returns the CNF of its negation—thus producing a resolution refutation of this CNF is equivalent to proving the original sequent. We actually get a set of resolution proofs witnessing that the clauses follow from the negation of the sequent:

\begin{verbatim}
gapt> val proofs = structuralCNF(hos":- ?z ?x (drinksat z x \rightarrow !y drinksat z y)"
val proofs: Set[gapt.proofs.resolution.ResolutionProof] =
Set([p4] \vdash \text{drinksat}(z, x) \text{(ImpL1(p3, Ant(0)))}
[p3] \text{drinksat}(z, x) \rightarrow \forall y \text{drinksat}(z, y) \vdash \text{(ExL(p2, Ant(0), x))}
[p2] \exists x \text{(drinksat}(z, x) \rightarrow \forall y \text{drinksat}(z, y)) \vdash \text{(ExL(p1, Ant(0), z))}
[p1] \exists z \forall x \text{(drinksat}(z, x) \rightarrow \forall y \text{drinksat}(z, y)) \vdash \text{(Input(\exists z \forall x \text{(drinksat}(z, x) \rightarrow \forall y \text{drinksat}(z, y)) \vdash ))}
, [p5] \text{drinksat}(z, s_0(z)) \vdash \text{(AllL(p4, Ant(0), s_0(z)))}
[p4] \forall y \text{drinksat}(z, y) \vdash \text{(ImpL2(p3, Ant(0)))}
[p3] \text{drinksat}(z, x) \rightarrow \forall y \text{drinksat}(z, y) \vdash \text{(ExL(p2, Ant(0), x))}
[p2] \exists x \text{(drinksat}(z, x) \rightarrow \forall y \text{drinksat}(z, y)) \vdash \text{(ExL(p1, Ant(0), z))}
[p1] \exists z \forall x \text{(drinksat}(z, x) \rightarrow \forall y \text{drinksat}(z, y)) \vdash \text{(Input(\exists z \forall x \text{(drinksat}(z, x) \rightarrow \forall y \text{drinksat}(z, y)) \vdash ))}
)\)
\end{verbatim}

25
Let us explain the terminology used in GAPT: in this example, we introduced the Skolem term \( s_0(z) \) for the universal quantifier \( \forall y \). This Skolem term has the Skolem constant \( s_0 \) and the Skolem definition \( \lambda z \forall y \text{drinksat}(z, y) \). The mapping from Skolem constants to Skolem definitions is stored in the Context, and is required to be acyclic. These definitions ensure that Skolemization is used in a sound way.

We represent Skolemization in proofs using Skolem inferences. For example in LK the \( \forall sk:r \) rule handles universal quantifiers. The corresponding rules also exist in resolution and expansion proofs.

\[
\Gamma \vdash \Delta, \varphi(s(t)) \\
\Gamma \vdash \Delta, \forall x \varphi(x) \quad \text{where } s \text{ has the Skolem definition } \lambda y D(y), \text{ and } D(t) = (\forall x \varphi(x))
\]

Given a proof that uses eigenvariables for strong quantifiers, we can replace the eigenvariable inferences by Skolem inference using skolemizeLK—this is called proof Skolemization:

```gapt
val p = ForallRightRule(ReflexivityAxiom(le"x"), hof"!x x=x")
```

By default, skolemizeLK will keep eigenvariable inferences above cuts. The function skolemize performs Skolemization on formulas. In the first-order case it is also possible to Skolemize proofs without introducing Skolem inferences, by modifying the end-sequent instead. This functionality is provided by the folSkolemize function.

## 4.4 Deskolemization

All automated provers integrated in GAPT introduce Skolem functions for strong quantifiers and return proofs with Skolem inferences as described in Section 4.3. The function deskolemizeET implements a variant of the expansion proof-based method for proof deskolemization described in [3] with an extension to support all forms of Skolemization allowed by Skolem definitions.

```gapt
val Some(p) = Escargot.getExpansionProof(hof”?x (drinks x -> !y drinks y)“)
```

By default, skolemizeLK will keep eigenvariable inferences above cuts. The function skolemize performs Skolemization on formulas. In the first-order case it is also possible to Skolemize proofs without introducing Skolem inferences, by modifying the end-sequent instead. This functionality is provided by the folSkolemize function.
In the worst case, deskolemization results in non-elementarily larger proofs [1].

4.5 Interpolation

The command ExtractInterpolant extracts an interpolant from an LK proof, based on Lemma 6.5 of [16]. The method expects a proof \( \pi \) and an arbitrary partition of the end-sequent \( \Gamma \vdash \Delta \) of \( \pi \) into a “negative part” \( \Gamma_1 \vdash \Delta_1 \) and a “positive part” \( \Gamma_2 \vdash \Delta_2 \). It returns a formula \( I \) such that \( \Gamma_1 \vdash \Delta_1, I \) and \( I, \Gamma_2 \vdash \Delta_2 \) are provable and \( I \) contains only such predicate symbols that appear in both partitions.

\[
\begin{align*}
\text{gapt> ExtractInterpolant(p, Seq(Suc(0)))} & \ \\
\text{val res0: gapt.expr.formula.Formula = } & \neg a \lor (\bot \lor c)
\end{align*}
\]

Here \( \text{Seq(Suc(0))} \) is the list of indices of the formulas that are in the positive partition. You can also get proofs of \( \Gamma_1 \vdash \Delta_1, I \) and \( I, \Gamma_2 \vdash \Delta_2 \) by using the Interpolate function.

4.6 LK to ND translation

GAPT supports translation of sequent calculus (Appendix B.1) proofs without Skolem inferences to natural deduction proofs (Appendix B.2). Consider the following example:

\[
\begin{align*}
\text{gapt> examples.gapticExamples.lemma} & \ \\
\text{val res0: gapt.proofs.lk.LKProof = } & \text{(LogicalAxiom(a:o))} & \\
\text{[p7] A \rightarrow B \vdash A \land B \lor \neg A } & \text{(OrRightRule(p6, Suc(0), Suc(1)))} & \\
\text{[p6] A \rightarrow B \vdash A \land B, \neg A } & \text{(NegRightRule(p5, Ant(0)))} & \\
\text{[p5] A, A \rightarrow B \vdash A \land B } & \text{(ContractionLeftRule(p4, Ant(2), Ant(0)))}
\end{align*}
\]
GAPT – User Manual

[p4] A, A → B, A ⊢ A ∧ B (AndRightRule(p1, Suc(0), p3, Suc(0)))
[p3] A → B, A ⊢ B (ImpLeftRule(p1, Suc(0), p2, Ant(0)))
[p2] B ⊢ B (LogicalAxiom(B:o))
[p1] A ⊢ A (LogicalAxiom(A:o))

gapt> LKToND( examples.gapticExamples.lemma, Some( Suc( 0 ) ) )
val res1: gapt.proofs.nd.NDProof =
[p15] A → B ⊢ A ∧ B ∨ ¬ A (ExcludedMiddleRule(p2, Ant(0), p14, Ant(0)))
[p14] ¬ (A ∧ B), A → B ⊢ A ∧ B ∨ ¬ A (OrIntro2Rule(p13, A ∧ B))
[p13] ¬ (A ∧ B), A → B ⊢ ¬ A (NegIntroRule(p12, Ant(1)))
[p12] ¬ (A ∧ B), A, A → B ⊢ ⊥ (NegElimRule(p3, p11))
[p11] A, A → B ⊢ A ∧ B (ContractionRule(p10, Ant(0), Ant(2)))
[p7] A → B ⊢ A → B (LogicalAxiom(A → B))
[p6] ⊢ B ⊢ B (LogicalAxiom(B:o))
[p5] A ⊢ A (LogicalAxiom(A:o))
[p4] A ⊢ A (LogicalAxiom(A:o))
[p3] ⊢ (A ∧ B) (LogicalAxiom(A ∧ B))
[p2] A ∧ B ⊢ A ∧ B ∨ ¬ A (OrIntro1Rule(p1, ¬ A))
[p1] A ∧ B ⊢ A ∧ B (LogicalAxiom(A ∧ B))

The LKToND function takes an LKProof, and optionally an Option[SequentIndex], as parameters. Because ND proofs can only contain a single formula in the succedent, the translation must focus on one of the formulas in the succedent of the LK proof that is to be proved in the ND proof. Thus, sometimes formulas need to be exchanged between the antecedents and succedents in the ND proof. This exchange is inherently classical and introduces the excluded middle rule into the proof.

4.7 Expansion proofs

Expansion proofs are a compact representation of the quantifier inferences in a proof. They have originally been introduced in [14]. GAPT contains an implementation of expansion proofs with cut for higher-order logic, including functions to extract expansion trees from proofs, to merge expansion trees, to prune and transform them in various ways, to eliminate first-order cuts, and to display them in the graphical user interface.

An expansion tree contains the instances of the quantifiers for a formula. In order to represent a proof of a sequent we use sequents of expansion trees. An expansion proof consists of such a sequent of expansion trees where the strong quantifiers do not form cycles. For example we can obtain an expansion proof by:

gapt> val expansion = LKToExpansionProof(examples.fol1.proof)
val expansion: gapt.proofs.expansion.ExpansionProof =
∀ X (X → X)
+ {∀x ∃y (¬ P(x, y) ∨ Q(x, y))}
\[(\forall x \, \exists y \, (\neg P(x, y) \lor Q(x, y)) \, +ev^x)\]

\[\exists y \, (\neg P(x, y) \lor Q(x, y)) \, +ev^y\]

\[\exists y \, (\neg P(x, a) \lor Q(x, a)) \, +\]

\[\forall x \, \exists y \, (\neg P(x, y) \lor Q(x, y)) \, +ev^x\]

\[\exists y \, (\neg P(x, y) \lor Q(x, y)) \, +ev^y\]

\[\forall x \, \exists y \, (\neg Q(x, y) \rightarrow \neg P(x, y)) \, +ev^x\]

\[\exists y \, (\neg Q(x, y) \rightarrow \neg P(x, y)) \, +ev^y\]

The expansion proof returned by LKToExpansionProof contains the quantifier inferences of the proof in LK and the quantified cuts. Quantifier-free cuts are not included, as they can never be involved in quantifier inferences.

Expansion proofs have shallow and deep sequents. The shallow sequent corresponds to the end-sequent of the proof in LK, and is the sequent that is proven. The deep sequent consists of instances of the shallow sequent: the (quasi-)tautology of the deep sequent implies the validity of the shallow sequent.

\gapt> expansion.shallow
\[\forall x \, \exists y \, (\neg P(x, y) \lor Q(x, y)) \, +ev^x\]

\gapt> expansion.deep
\[\exists y \, (\neg Q(x, y) \rightarrow \neg P(x, y)) \, +ev^y\]

The expansion proof contains a cut. Cuts are stored as expansions of the second-order formula \(\forall X (X \rightarrow X)\) in the antecedent. GAPT contains a procedure to eliminate such cuts in expansion proofs as described in [13]:

\gapt> eliminateCutsET(expansion)
\[\forall x \, \exists y \, (\neg Q(x, y) \rightarrow \neg P(x, y)) \, +ev^y\]

We can also convert expansion proofs to LK; this works even in the presence of cuts, and also if the proof requires equational reasoning:

\gapt> ExpansionProofToLK(expansion).get
\[\forall x \, \forall y \, (\neg P(x, y) \lor Q(x, y)) \, +ev^x\]

\[\forall x \, \exists y \, (\neg Q(x, y) \rightarrow \neg P(x, y)) \, +ev^y\]

\[\forall x \, \exists y \, (\neg Q(x, y) \rightarrow \neg P(x, y)) \, +ev^y\]
You can also view this expansion proof in the graphical user interface in a convenient and flexible way by calling:

```
gapt> prooftool(expansion)
```

A window then opens that displays the shallow sequent of expansion. You can selectively expand quantifiers by clicking on them, see [12] for a detailed description.

### 4.8 Modified realizability

The GAPT-system contains an implementation of modified realizability for first-order logic. This is a variant of realizability where the realizers are terms of system $T$: an extension of the simply typed lambda calculus with inductive types and recursors that allow for recursive computation over terms of those types.

The implementation extracts realizers for theorems from their proofs in the natural deduction calculus (Appendix B.2). If the conclusion of the proof depends on a number of hypothesis, i.e. there are formulas $A_1, \ldots, A_n$ in the antecedent of the final sequent, the algorithm returns a term $M$ with free variables $x_1, \ldots, x_n$ such that $M[M_1/x_1] \ldots [M_n/x_n]$ is a realizer for the succedent, where $M_i$ realizes $A_i$. The formulas in the conclusion are also allowed to have free variables. In this case, the substitution of free variables in both the formulas and its realizer by the same closed terms, gives a realizer for the resulting sentence.

The natural deduction calculus contains two rules that are problematic for the extraction of realizers, namely the theory axiom, which can be instantiated by any formula, and a rule for the lemma of the excluded middle. When these are used, a realizer can not be computed — it might not even exists. In the case of the theory axiom, we would need a realizer for the theorem that is introduced by the axiom, and for the excluded middle rule, we would need a realizer for $A \lor \neg A$ to compute the realizer for the conclusion of the rule. When $A$ is the formula for which a realizer is needed, these rules therefore introduce a free variable (named $\text{mrealizer}(A)$) in the resulting realizer, that serves as a placeholders for a realizer for $A$.

Any other free variable occurring in an extracted realizer, that is not the result of any of the above situations, must be understood to mean that it may be replaced by any term of the type of the variable.

Consider the following proof:

```gapt>
```

```
gapt> val p = examples.successor.proof
```

```
val p: gapt.proofs.nd.ForallIntroRule =
```
The implementation can then be used to extract a realizer in the following way:

```
gapt> val mr = nd.MRealizability.mrealize(p)(examples.successor.ctx)
val mr: (Map[gapt.proofs.SequentIndex,gapt.expr.Var], gapt.expr.Expr) = (Map(),λ x s(x:nat ): nat)
```

Examples of proofs with from which more interesting realizers are extracted by the algorithm can be found in the file examples/m-realizabilityExamples.scala.
Chapter 5

Input and output

GAPT can read from and write to several existing formats, including JSON and TPTP.

5.1 JSON

GAPT currently supports JSON import and export of LK proofs and expansion proofs, as well as all of their components such as formulas, sequents, indices, etc. For instance, this is how you export a sequent to JSON:

```
gapt> val s = JsonExporter(hos"A, B := P(x)").render(80)
val s: String = "{antecedent" : ["A:o", "B:o"], "succedent" : ["P(x): o"]}
```

To read the JSON string back into a sequent:

```
gapt> val sequent = JsonImporter.load[HOLSequent](InputFile.fromString(s))
val sequent: gapt.proofs.HOLSequent = A, B ⊢ P(x)
```

Serializing an LK proof to JSON works a little differently than you might expect. Instead of naively serializing the proof as an object, its distinct subproofs are collected in a map.

```
gapt> val ax1 = LogicalAxiom(hof"A")

gapt> val ax2 = LogicalAxiom(hof"B")
val ax2: gapt.proofs.lk.rules.LogicalAxiom = [p1] B ⊢ B (LogicalAxiom(B:o))

gapt> val p1 = AndRightRule(ax1, hof"A", ax2, hof"B")
val p1: gapt.proofs.lk.rules.AndRightRule = [p3] A, B ⊢ A ∧ B (AndRightRule(p1, Suc(0), p2, Suc(0)))
[p2] B ⊢ B (LogicalAxiom(B:o))
[p1] A ⊢ A (LogicalAxiom(A:o))
```
As you can see, each of the logical axioms is only serialized once, despite being used multiple times in the proof.
5.2 TPTP

You can export sequents as TPTP problems:

```gapt
GAPT> val sequent = hos"p(0), !x (p(x) -> p(s(x))) :- p(s(s(0)))"
val sequent: gapt.proofs.HOLSequent = p(0), \forall x (p(x) \rightarrow p(s(x))) \vdash p(s(s(0)))
GAPT> TptpFOLExporter(sequent)
val res0: gapt.formats.tptp.TptpFile =
fof(ant_0, axiom, p(\Var{0})).
fof(ant_1, axiom, \![X]: (p(X) \Rightarrow p(s(X)))).
fof(suc_0, conjecture, p(s(s(\Var{0}))))).
```

You can also parse TPTP problems:

```gapt
GAPT> val tptp = TptpImporter.loadWithIncludes("examples/import/irrationals.p")
val tptp: gapt.formats.tptp.TptpFile =
fof(a, axiom, i(sr2)).
fof(b, axiom, \neg i(two)).
fof(c, axiom, times(sr2, sr2) = two).
fof(d, axiom, \![X,Y,Z]: exp(exp(X, Y), Z) = exp(X, times(Y, Z)))).
fof(e, axiom, \![X]: exp(X, two) = times(X, X)).
fof(f, conjecture, ?[X,Y]: (\neg i(exp(X, Y)) & i(X) & i(Y))).
```

```gapt
GAPT> tptp.toSequent
val res2: gapt.proofs.HOLSequent =
i(sr2),
\neg i(two),
times(sr2, sr2) = two,
\forall X \forall Y \forall Z exp(exp(X, Y), Z) = exp(X, times(Y, Z)),
\forall X exp(X, two) = times(X, X)
\vdash 
\exists X \exists Y (\neg i(exp(X, Y)) \land i(X) \land i(Y))
```
Chapter 6

Interfaces to external theorem provers and solvers

6.1 First-order theorem provers

GAPT includes interfaces to several first-order theorem provers, such as Prover9, E prover, and LeanCoP. For Vampire, SPASS, E, Prover9, and Metis we can read back resolution proofs, and construct LK and expansion proofs from them. The LeanCoP interface reads back expansion proofs (and converts them to LK if desired).

Here is how you can get all of these kinds of proofs using Prover9:

```gapt
val sequent = hols"p(0), !x (p(x) \rightarrow p(s(x))) :- p(s(s(0)))"
val sequent: gapt.proofs.HOLSequent = p(0), \forall x (p(x) \rightarrow p(s(x))) \implies p(s(s(0)))

gapt> Prover9 isValid sequent
val res0: Boolean = true

gapt> Prover9 getResolutionProof sequent
\implies (Resolution(p8, Suc(0), p12, Ant(0))))
[p12] p(s(0)) \implies (Resolution(p9, Suc(0), p11, Ant(0))))
[p11] p(s(s(0))) \implies (Subst(p10, Substitution()))
[p10] p(s(s(0))) \implies (Input(p(s(s(0))) \implies ))
[p9] p(s(0)) \implies p(s(s(0))) (Subst(p6, Substitution(v0 -> s(0))))
[p8] \implies p(s(0)) (Resolution(p2, Suc(0), p7, Ant(0))))
[p7] p(0) \implies p(s(0)) (Subst(p6, Substitution(v0 -> 0)))
[p6] p(v0) \implies p(s(v0)) (Subst(p5, Substitution(x -> v0)))
[p5] p(x) \implies p(s(x)) (ImpR(p4, Suc(0))))
[p4] \implies p(x) \rightarrow p(s(x)) (AllR(p3, Suc(0), x))
[p3] \forall x (p(x) \rightarrow p(s(x))) (Input( \implies \forall x (p(x) \rightarrow p(s(x)))))
[p2] \implies p(0) (Subst(p1, Substitution()))
[p1] \implies p(0) (Input( \implies p(0)))
```

37
gapt> Prover9 getLKProof sequent
val res2: Option[gapt.proofs.lk.LKProof] = Some(  
[p10] p(0), ∀x (p(x) → p(s(x))), p(0) ⊢ p(s(0)) (ContractionLeftRule(p10, Ant(2), Ant(1)))  
[p9] ∀x (p(x) → p(s(x))), p(0) ⊢ p(s(0)) (CutRule(p8, Suc(0), p6, Ant(0)))  
[p8] ∀x (p(x) → p(s(x))), p(0) ⊢ p(s(0)) (ForallLeftRule(p7, Ant(0), p(x) → p(s(x)), s(0), x))  
[p7] p(s(0)) → p(s(s(0))), p(0) ⊢ p(s(0)) (ImpLeftRule(p2, Suc(0), p6, Ant(0)))  
[p6] p(s(0)) ⊢ p(s(0)) (LogicalAxiom(p(s(0)): o))  
[p5] p(0), ∀x (p(x) → p(s(x))) ⊢ p(s(0)) (CutRule(p1, Suc(0), p4, Ant(1)))  
[p4] ∀x (p(x) → p(s(x))), p(0) ⊢ p(s(0)) (ForallLeftRule(p3, Ant(0), p(x) → p(s(x)), 0, x))  
[p3] p(0) → p(s(0)), p(0) ⊢ p(s(0)) (Imp...  
)

All of the above works with the E prover (EProver), SPASS (SPASS), Vampire (Vampire), and Metis (Metis) as well, we will just show EProver.getLKProof as an example:

...
∃x ∀y p(x, y) +skˈs_0) ∀y p(s_0, y) +ˈs_1) p(s_0, s_1) →
∀y ∃x p(x, y) +skˈs_1) ∃x p(x, s_1) +ˈs_0) p(s_0, s_1) +)

The LeanCoP interface supports `getExpansionProof` as well:

```gapt
val res6: Option[gapt.proofs.expansion.ExpansionProof] =
Some(∀x (p(x) → p(s(x))) +ˈ{0) (p(0) → p(s(0))+) +ˈ(s(0)) (p(s(0)) + → p(s(s(0)))→),
p(0)→
:p(s(s(0)))+)
```

For treating problems in many-sorted first-order logic with a prover that supports only standard (one-sorted) first-order logic, GAPT provides appropriate reductions. For example, we can obtain a many-sorted expansion proof from Prover9 (which only supports a single sort) in the following way:

```gapt
val reduction = PredicateReductionET |> ErasureReductionET
```

```gapt
val problem = hos"!(x:a)!y x=y, !x f(f(x:b))=x :- ?y c=f(y)"
val problem: gapt.proofs.HOLSequent =
∀x ∀y (x:a) = (y:a), ∀x f(f(x:b): b) = x ⊢ ∃y (c:b) = f(y)
```

```gapt
val firstOrderProblem, back = reduction forward problem
val firstOrderProblem: gapt.proofs.HOLSequent =
∀x0 (P_is_b(x0) → P_is_b(f_f(x0))),
⊤ → P_is_b(f_c),
∃x P_is_b(x),
∃x P_is_a(x),
∀x (P_is_a(x) → ∀y (P_is_a(y) → x = y)),
∀x (P_is_b(x) → f_f(f_f(x)) = x)
⊤
∃y (P_is_b(y) ∧ f_c = f_f(y))
```

```gapt
Escarbot getExpansionProof firstOrderProblem map back
val res7: Option[gapt.proofs.expansion.ExpansionProof] =
Some(∀x f(f(x:b): b) = x +ˈ{c) (f(f(c)) = c)-
:-
∃y (c:b) = (f(y:b): b) +ˈ{f(c)) (c = f(f(c)))+)
```

### 6.2 SMT solvers

The SMT solver interface in GAPT supports validity queries for QF_UF formulas. For example we can check whether a quantifier-free formula is a quasi-tautology using veriT:
GAPT – User Manual

```gapt
gapc> val f = hof"(a=b | a=c) & P(c) & P(b) -> P(a)"
val f: gapt.expr.formula.Formula = (a = b ∨ a = c) ∧ P(c) ∧ P(b) → P(a)

gapc> VeriT isValid f
val res0: Boolean = true

GAPT also supports Z3 and CVC4 out of the box (if they are installed):

gapc> Z3 isValid f
val res1: Boolean = true

gapc> CVC4 isValid f
val res2: Boolean = true

You can export QF_UF formulas (or sequents) as SMT-LIB benchmarks; note that we apply a drastic renaming to the constant symbols in order to support arbitrary (even Unicode) names in GAPT:

gapc> val (benchmark, typeRenaming, constantRenaming) = SmtLibExporter(Sequent() :+ f)
val benchmark: String = "(set-logic QF_UF)
(declare-sort t_i 0)
(declare-fun f_P (t_i) Bool)
(declare-fun f_c () t_i)
(declare-fun f_a () t_i)
(declare-fun f_b () t_i)
(assert
(not
(=> (and (and (or (= f_a f_b) (= f_a f_c)) (f_P f_c)) (f_P f_b))
       (f_P f_a))))
(check-sat)
"
val typeRenaming: Map[gapt.expr.ty.TBase,gapt.expr.ty.TBase] = Map(o -> Bool, i -> t_i)
val constantRenaming: Map[gapt.expr.Const,gapt.expr.Const] = Map(a -> f_a:t_i, b -> f_b:t_i, c -> f_c:t_i, P:i>o -> f_P:t_i>Bool)

We can also extract instances for basic equality axioms (reflexivity, symmetry, and congruences) from veriT’s proof output:

gapc> val Some(expansionProof) = VeriT getExpansionProof f
val expansionProof: gapt.proofs.expansion.ExpansionProof = ∀x ∀y (x = y → y = x)
+"{a, b} ((a = b)+ → (b = a)-),
+"{a, c} ((a = c)+ → (c = a)-),
∀x0 ∀y0 (x0 = y0 ∧ P(x0) → P(y0))
+"{b, a} ((b = a)+ ∧ P(b)+ → P(a)-)
+"{c, a} ((c = a)+ ∧ P(c)+ → P(a)-)
:="
((a = b)+ ∨ (a = c)-) ∧ P(c)- ∧ P(b)- → P(a)+

gapc> extractInstances(expansionProof) foreach println
a = c → c = a
```

40
6.3 SAT solvers

The following shows an example session, using the Sat4j SAT solver to verify validity and satisfiability, and query the thus obtained models. Consider the pigeon hole principle for \((m, n)\), PHP\(_{m,n}\), which states that if \(m\) pigeons are put into \(n\) holes, then there is a hole which contains two pigeons. It is valid iff \(m > n\). \(\neg\)PHP\(_{m,n}\) states that when putting \(m\) pigeons into \(n\) holes, there is no hole containing two pigeons. This is satisfiable iff \(m \leq n\).

```gapt
val res0: Boolean = true
```
shows\(^1\) that PHP\(_{3,2}\) is valid, and

```gapt
val res1: Boolean = false
```
shows that PHP\(_{3,3}\) is not valid. Furthermore,

```gapt
val m: gapt.models.PropositionalModel =
R(p_1, h_1): o -> true
R(p_1, h_2): o -> false
R(p_1, h_3): o -> false
R(p_2, h_1): o -> false
R(p_2, h_2): o -> true
R(p_2, h_3): o -> false
R(p_3, h_1): o -> false
R(p_3, h_2): o -> false
R(p_3, h_3): o -> true
```
yields a model of \(\neg\)PHP\(_{3,3}\) that can be queried:

```gapt
val p1 = PigeonHolePrinciple.inHole(1, 1)
val p1: gapt.expr.formula.fol.FOLAtom = R(p_1, h_1): o
```

```gapt
val p2 = PigeonHolePrinciple.inHole(2, 1)
val p2: gapt.expr.formula.fol.FOLAtom = R(p_2, h_1): o
```

```gapt
m(p1) // Is pigeon 1 in hole 1?
val res2: Boolean = true
```

```gapt
m(p2) // Is pigeon 2 in hole 1?
val res3: Boolean = false
```

\(^1\)In Scala, Sat4j isValid formula is syntactic sugar for Sat4j.isValid(formula).

We can also interpret quantifier-free formulas:

```gapt
gapt> m( And(p1, p2) )
val res4: Boolean = false
```

We can also convert ¬PHP₃,₃ into DIMACS format:

```gapt
gapt> val cnf = structuralCNF(Sequent() :+ PigeonHolePrinciple(3,3)).map(_.conclusion.
              asInstanceOf[ HolClause ])
val cnf: scala.collection.immutable.Set[ gapt.proofs.HOLClause ] = 
HashSet( ⊢ R(p_3, h_3), R(p_3, h_1), R(p_3, h_2), R(p_1, h_2), R(p_3, h_2) ⊥ , R(p_1, h_2), R(p_2, h_2) ⊥ , R(p_1, h_3), R(p_2, h_3) ⊥ , R(p_2, h_1), R(p_3, h_1) ⊥ , ⊢ R(p_1, h_3), R(p_1, h_1), R(p_1, h_2), R(p_2, h_1), R(p_1, h_1), R(p_2, h_1), R(p_3, h_1) ⊥ , ⊢ R(p_2, h_3), R(p_2, h_1), R(p_2, h_2), R(p_1, h_3), R(p_3, h_3) ⊥ , R(p_2, h_3), R(p_3, h_3) ⊥ , ⊢ R(p_2, h_2), R(p_3, h_2) ⊥ )
```

```gapt
gapt> val encoding = new DIMACSEncoding
val encoding: gapt.formats.dimacs.DIMACSEncoding = DIMACSEncoding()
```

```gapt
gapt> writeDIMACS(encoding encodeCNF cnf)
val res5: String =
p cnf 9 12
-9 -2 0
7 8 5 0
1 2 3 0
-8 -2 0
-9 -8 0
-4 -5 0
-5 -3 0
-6 -1 0
-6 -7 0
-4 -3 0
-7 -1 0
6 9 4 0
```

If you want to know which variable in the DIMACS output corresponds to which atom in GAPT, you can query the DIMACSEncoding object:

```gapt
gapt> encoding decodeAtom 1
val res6: gapt.expr.formula.Atom = R(p_3, h_3): o
```

GAPT also supports other SAT solvers such as MiniSAT or Glucose out of the box:

```gapt
gapt> MiniSAT isValid PigeonHolePrinciple(3,2)
val res7: Boolean = true
```

```gapt
gapt> Glucose isValid PigeonHolePrinciple(3,2)
val res8: Boolean = true
```

If you have another DIMACS-compliant solver installed or want to pass extra options to the SAT solver, you can pass a custom command to GAPT as well:
gapt> val solver = new ExternalSATSolver("minisat", ",-mem-lim=1024")
val solver: gapt.provers.sat.ExternalSATSolver = ExternalSATSolver("minisat", ",-mem-lim=1024")

gapt> solver isValid PigeonHolePrinciple(3,2)
val res9: Boolean = true

GAPT can import DRUP proofs from Sat4j, Glucose, and PicoSAT:

```
gapt> Sat4j getDrupProof PigeonHolePrinciple(4,3)
val res10: Option[gapt.proofs.rup.RupProof] =
Some(c input 12 11 8 0
  c input -1 -2 0
  c input -4 -8 0
  c input 7 9 1 0
  c input -9 -6 0
  c input -9 -3 0
  c input -11 -5 0
  c input -5 -2 0
  c input -10 -8 0
  c input -7 -8 0
  c input -1 -5 0
  c input -4 -10 0
  c input -7 -4 0
  c input -3 -12 0
  c input -3 -6 0
  c input 6 10 2 0
  c input -9 -12 0
  c input -6 -12 0
  c input -11 -2 0
  c input -7 -10 0
  c input 3 4 5 0
  c input -11 -1 0
  -8 1 0
  -9 8 0
  -11 10 4 0
  1 0
-12 0
0)
```

Just as in the first-order prover interface (see Section 6.1), you can call getResolutionProof and getLKProof to get the proofs in the desired format:

```
gapt> Sat4j getLKProof PigeonHolePrinciple(4,3)
val res11: Option[gapt.proofs.lk.LKProof] =
Some([p575]
|- (R(p_1, h_1) \lor R(p_1, h_2) \lor R(p_1, h_3)) \land
  (R(p_2, h_1) \lor R(p_2, h_2) \lor R(p_2, h_3)) \land
  (R(p_3, h_1) \lor R(p_3, h_2) \lor R(p_3, h_3)) \land
  (R(p_4, h_1) \lor R(p_4, h_2) \lor R(p_4, h_3)) \rightarrow
```

43
6.4 MaxSAT solvers

The MaxSAT interface supports generating optimal solutions for weighted partial MaxSAT instances: these consist of a list of hard clauses, which must be satisfied in the solution; and a list of weighted soft clauses, where weight of the satisfied soft clauses must be maximized. See [2] for an overview.

Let us solve a simple example using the MaxSAT solver from SAT4J:

```scala
gapt> MaxSat4j.solve(hard = hof"a|b|c", soft = Seq(hof"-a" -> 4, hof"-b" -> 3))
val res0: Option[gapt.models.PropositionalModel] =
Some(a:o -> false
   b:o -> false
   c:o -> true)
```

GAPT also supports other MaxSAT solvers out of the box, just write OpenWBO or ToySolver instead of MaxSat4j.
Chapter 7

Built-in theorem provers

7.1 The superposition prover escargot

GAPT contains a simple built-in superposition prover called Escargot. It is used for proof replay to import proofs from other provers. You can use it with the same interface as Prover9 and the other first-order provers:

```gapt
val formula = fof"!x!y!z (x+y)+z=x+(y+z) & !x!y x+y=y+x -> d+a+c+b=a+b+c+d"
val formula: gapt.expr.formula.fol.FOLFormula =
\forall x \forall y \forall z x + y + z = x + (y + z) \land \forall x \forall y x + y = y + x ->
d + a + c + b = a + b + c + d

val axiom = hof"P(nil) & !x!y!z (P(x) -> P(y))"
val axiom: gapt.expr.formula.Formula = P(nil) \land \forall x \forall y \forall z (P(x) \rightarrow P(y))
```

Escargot can natively solve many-sorted problems, for example:

```gapt
val formula = fof"P(cons(0:nat, cons(s(0), nil): list))"
val formula: gapt.expr.formula.Formula = P(cons(0:nat, cons(s(0): nat, nil:list): list)):
  o

val axiom = hof"P(nil) & !x!y!z (P(x) \rightarrow P(y))"
val axiom: gapt.expr.formula.Formula = P(nil) \land \forall x \forall y \forall z (P(x) \rightarrow P(y))
```
Val axiom: gapt.expr.formula.Formula = P(nil:list) ∧ ∀x ∀y ∀z (P(x) → P(cons(y:nat, cons(z:nat, x): list)))

gapt> val problem = hof"axiom -> $formula"
val problem: gapt.expr.formula.Formula = P(nil:list) ∧ ∀x ∀y ∀z (P(x) → P(cons(y:nat, cons(z:nat, x): list))) → P(cons(0, cons(s(0), nil)))

gapt> Escargot.getExpansionProof(problem)
val res1: Option[gapt.proofs.expansion.ExpansionProof] = Some(
  :-
P(nil:list)∧ ∀x ∀y ∀z (P(x) → P(cons(y:nat, cons(z:nat, x): list))) ∨ P(nil)+→ P(cons(0, cons(s(0), nil))))

Escargot can also be used from the command-line using the escargot.sh script. This script expects a problem in TPTP format:

$ ./escargot.sh examples/tptp/SET001-1.p

7.2 The inductive theorem prover viper

GAPT contains a built-in inductive theorem prover: Viper (Vienna inductive theorem prover). It can be started from the command line using the viper.sh script. It takes input in the TIP format [6]. Viper has a mode for analytic induction and a mode for the tree grammar-based method described in [8]. As of version 2.8 of GAPT, viper is in an early stage of development. By default, the viper.sh scripts tries several different strategies to solve the given problem, including analytic induction and tree-grammar-based methods. The --help argument shows the available options.

$ ./viper.sh --treegrammar --cansolsize 2 3 --gramw scomp \examples/induction/prod_prop_31.smt2

You can also use Viper from within GAPT:

gapt> val problem = TipSmtImporter.load("examples/tip/isaplanner/prop_06.smt2")
val problem: gapt.formats.tip.TipProblem =
∀x0 'proj1-S'(S(x0)) = x0,
∀y '²')(Z, y) = Z,
∀z '²'Z)(S(z), Z) = S(z),
∀z ∀x2 '²'(S(z), S(x2)) = '²'(z, x2),
∀y '²'+Z)(Z, y) = y,
∀y ∀z '²'+S(z), y) = S('²'+Z, y)),
∀y0 Z ! = S(y0)
|-> ∀n ∀m '²'(n, '²'+n, m)) = Z
7.3 Built-in tableaux prover

GAPT contains a built-in tableaux prover for propositional logic which can be called with the command solvePropositional, for example as in:

```
gapt> solvePropositional(hof"a -> b -> a&b").get
```

```
val res0: gapt.proofs.lk.LKProof = [p5]
\[ \vdash a \rightarrow b \rightarrow a \land b \] (ImpRightRule(p4, Ant(0), Suc(0)))
[p4] a \vdash b \rightarrow a \land b (ImpRightRule(p3, Ant(1), Suc(0)))
[p3] a, b \vdash a \land b (AndRightRule(p1, Suc(0), p2, Suc(0)))
[p2] b \vdash b (LogicalAxiom(b:o))
[p1] a \vdash a (LogicalAxiom(a:o))
```

The tableaux prover can also prove quasi-tautologies if you call it as solveQuasiPropositional:

```
gapt> solveQuasiPropositional(hof"a = b & f a = b -> a = f(f(b))").get
```

```
val res1: gapt.proofs.lk.LKProof = [p9]
\[ \vdash a = b \land f(a) = a \rightarrow a = f(f(b)) \] (ImpRightRule(p8, Ant(0), Suc(0)))
[p8] a = b \land f(a) = a \vdash a = f(f(b)) (AndLeftRule(p7, Ant(1), Ant(0)))
[p7] f(a) = b, a = b \vdash a = f(f(b)) (EqualityLeftRule(p6, Ant(0), Ant(1), \lambda x f(a) = x))
[p6] a = b, f(a) = a \vdash a = f(f(b)) (EqualityRightRule(p5, Ant(0), Suc(0), \lambda x a = f(f(x))))
[p5] a = b, f(a) = a \vdash a = f(f(a)) (WeakeningLeftRule(p4, a = b))
[p4] f(a) = a \vdash a = f(f(a)) (EqualityRightRule(p3, Ant(0), Suc(0), \lambda x a = f(x)))
[p3] f(a) = a \vdash a = f(a) (EqualityRightRule(p2, Ant(0), Suc(0), \lambda x a = x))
```
7.4 Intuitionistic theorem prover Slakje

Slakje is an automated intuitionistic theorem prover based on constructivization of classical proofs on the level of expansion trees. The function `Slakje.getLKProof` returns a cut-free intuitionistic proof in the calculus LJ:

```gapt
val res0: Option[gapt.proofs.lk.LKProof] = Some([^p8] ⊢ ¬ ¬ ∀ x P(x) → ∀ x ¬ ¬ P(x) (ImpRightRule(p7, Ant(0), Suc(0)))
[^p7] ¬ ¬ ∀ x P(x) ⊢ ∀ x ¬ ¬ P(x) (ForallRightRule(p6, Suc(0), v, x))
[^p6] ¬ ¬ ∀ x P(x) ⊢ ¬ ¬ P(v) (NegRightRule(p5, Ant(1)))
[^p5] ¬ ¬ ∀ x P(x), ¬ P(v) ⊢ (NegLeftRule(p4, Suc(0)))
[^p4] ¬ P(v) ⊢ ¬ ∀ x P(x) (NegRightRule(p3, Ant(1)))
[^p3] ¬ P(v), ∀ x P(x) ⊢ (NegLeftRule(p2, Suc(0)))
[^p2] ∀ x P(x) ⊢ P(v) (ForallLeftRule(p1, Ant(0), P(x): o, v, x))
[^p1] P(v) ⊢ P(v) (LogicalAxiom(P(v): o))
)
```

Slakje can also be used from the command-line using the `slakje.sh` script. This script expects a problem in TPTP format:

```
$ ./slakje.sh examples/tptp/LCL684+1.001.p
```
Chapter 8

Advanced topics

8.1 Cut-elimination by resolution (CERES)

Cut-elimination by resolution (CERES) is a method which transforms a proof with arbitrary cut-formulas into one with only atomic cuts \([4, 5]\). Since expansion proofs can be extracted directly from a proof with quantifier-free cut-formulas, we can skip the elimination of atomic cuts.

For instance, the example proof Pi2Pigeonhole formalizes the fact that given an aviary with two holes and an infinite number of pigeons, one hole has to house at least two pigeons. The pigeons and the holes are represented by numerals in unary notation with zero 0 and successor s. The function symbol \(f\) maps pigeons to holes, which allows us to state the mapping of pigeons to holes as \(\forall x(f(x) = 0 \lor f(x) = s(0))\). The actual statement to prove is then \(\exists x \exists y(s(x) \leq y \land f(x) = f(y))\).

In order to prove it we also need to axiomatize \(\leq\) with \(\forall x \forall y(s(x) \leq y \rightarrow x \leq y)\) and a maximum function \(M\) with \(\forall x \forall y(x \leq M(x, y) \land y \leq M(x, y))\).

We can extract the cut formulas using the cutFormulas command and find two cuts on quantified formulas: \(\forall x \exists y(x \leq y \land f(y) = s(0))\) and \(\forall x \exists y(x \leq y \land f(y) = 0)\). This corresponds to a case distinction for each of the two holes which may contain the collision. The actual simplification is performed using the CERES command. Please note that the input proof must be regular and have a Skolemized end-sequent. The commands regularize and skolemize provide this functionality, if necessary.

```gapt
> prooftool(Pi2Pigeonhole.proof)

> cutFormulas(Pi2Pigeonhole.proof) filter {containsQuantifier(_)} foreach println
\(\forall x \exists y (x \leq y \land f(y) = s(0))\)
\(\forall x \exists y (x \leq y \land f(y) = 0)\)

> val acnf = CERES(Pi2Pigeonhole.proof)
val acnf: gapt.proofs.lk.LKProof =
[p366] \(\forall x \forall y (x \leq M(x, y) \land y \leq M(x, y))\),
\(\forall x (f(x) = 0 \lor f(x) = s(0))\)
\(\vdash \exists x \exists y_0 (s(x) \leq y_0 \land f(x) = f(y_0))\) (ContractionRightRule(p365, Suc(1), Suc(0)))
```

∀x (f(x) = 0 ∨ f(x) = s(0))
⊢
∃y_0 (s(x) <= y_0 ∧ f(x) = f(y_0)),
(ContractionLeftRule(p365, Ant(2), Ant(1)))

8.2 Cut-introduction

The cut-introduction algorithm as described in [11, 10, 9] is implemented in GAPT for introducing
Π1-cuts into a sequent calculus proof. Take a cut-free example proof:

gapt> val p = LinearExampleProof(9)
val p: gapt.proofs.lk.LKProof =
∀x (P(x) → P(s(x))), P(0) ⊢ P(s(s(s(s(s(s(s(s(0)))))))))) (ContractionLeftRule(p35, Ant(0), Ant(1)))
∀x (P(x) → P(s(x))), P(0) ⊢ P(s(s(s(s(s(s(s(s(s(0)))))))))) (ForallLeftRule(p34, Ant(0), P(s(x) → P(s(x))), s(s(s(s(s(s(s(s(0))))))))), x))
P(s(s(s(s(s(s(s(s(0))))))))) → P(s(s(s(s(s(s(s(s(s(0)))))))))) (ContractionLeftRule(p33, Ant(0), Ant(1)))
P(s(s(s(s(s(s(s(s(0)))))))))) (ForallLeftRule(p32, Ant(2), P(s(s(s(s(s(s(s(s(0))))))))))...
8.3 Tree grammars

The cut-introduction method described in Section 8.2 is based on the use of certain tree grammars for representing Herbrand-disjunctions. These are totally rigid acyclic tree grammars (TRATGs) and vectorial TRATGs (VTRATGs). As shown in [10], these grammars are intimately related to the structure of proofs with cuts. GAPT contains an implementation of these tree grammars, and given a finite tree language (i.e., a set of terms), is able to automatically find a (V)TRATG that covers this language:

```gapt
val lang = 1 to 18 map { Numeral(_) }
val grammar = findMinimalVTRATG(lang.toSet, 2)
```

You can also find minimal sub-grammars that still generate certain terms:

```gapt
val grammar = findMinimalVTRATG(lang.toSet, 2)
```

You can also find minimal sub-grammars that still generate certain terms:
8.4 Formula equations

A formula equation is a first-order formula $F[X_1, \ldots, X_n]$ with free second-order predicate variables $X_1/k_1, \ldots, X_n/k_n$. A solution of a formula equation $F[X_1, \ldots, X_n]$ is a vector of first-order formulas $(G_1[x_1, \ldots, x_{k_1}], \ldots, G_n[x_1, \ldots, x_{k_n}])$ such that $F[X_1/G_1, \ldots, X_n/G_n]$ is valid. GAPT supports solving certain classes of formula equations. For example let

```
gapt> val F = hof"X(a) ∧ X(b)"
val F: gapt.expr.formula.Formula = X(a) ∧ X(b)
```

We can solve the formula equation above by

```
gapt> val scala.util.Success(s) = solveFormulaEquation(F)
val s: gapt.expr.subst.Substitution = Substitution(X:i>o -> λ x_0 a = x_0 ∨ b = x_0)
```

On success a substitution is returned, which when applied to the input formula yields a valid formula.

```
gapt> Escargot.isValid( BetaReduction.betaNormalize( s(F) ) )
val res0: Boolean = true
```

If solveFormulaEquation fails to find a solution, this does not mean that the formula equation is not solvable, but only that the algorithm we use could not find it.

The function solveFormulaEquation proceeds by a reduction to the related problem of finding first-order formulas $G_i$ such that

$$
∃X_1 \ldots ∃X_n F ↔ F[X_1/G_1, \ldots, X_n/G_n] \quad (8.1)
$$

is valid. This problem is a variant of second-order quantifier elimination. The DLS algorithm [7] can eliminate second-order quantifiers for certain formulas by computing equivalent first-order formulas. GAPT contains an implementation of a variant of the DLS algorithm that computes actual witnesses for second-order quantifiers. For example consider the following formula

```
gapt> val H = hof"?X ?Y( X(a) ∧ ¬ Y(a) )"
val H: gapt.expr.formula.Formula = ∃X ∃Y (X(a) ∧ ¬ Y(a))
```

We can eliminate the second-order quantifiers and obtain witnesses by
GAPT – User Manual

```scala
val scala.util.Success( (solution, folPart) ) = dls(H)
val solution: gapt.expr.subst.Substitution = Substitution(X:i>o -> \(x_0\) a = \(x_0\), Y:i>o -> \(\lambda\_0\) ⊥)
val folPart: gapt.expr.formula.Formula = X(a) ∧ ¬ Y(a)
```

The returned value is a tuple of a substitution and the possibly simplified first-order part of the input formula such that applying the substitution to the first-order part fulfils (8.1).

```scala
val Escargot.isValid(BetaReduction.betaNormalize(solution(folPart)))
```

```
val res1: Boolean = true
```

Again, failure of the method does not mean that there is no witness such that the equivalence holds, but merely that our algorithm could not find a witness. A more detailed description of the formulas that can be solved by our implementation of the DLS algorithm can be found in the documentation of dls.
Appendix A

Lambda calculus

GAPT uses a polymorphic simply-typed lambda calculus to represent formulas and terms. The syntax of types and terms is as follows. A type is either a type function, an arrow (function) type or a type variable.

\[
\text{Type ::= } f(\text{Type}, \ldots, \text{Type}) \mid \text{Type} \to \text{Type} \mid \alpha
\]

There are 4 kinds of expressions: constants, variables, applications, and abstractions:

\[
\text{Expr ::= } v : \text{Type} \mid c_{\text{Type} \ldots \text{Type}} : \text{Type} \mid \text{Expr Expr} \mid \lambda(v : \text{Type}) \text{Expr}
\]

This lambda calculus is simply typed in the sense that we do not have quantification over types. Instead, we allow inductive data types and definitions to be polymorphic. That is, data types and the types of definitions can have type variables. Constants have a list of type parameters; the name of a constant together with its parameters should uniquely determine the type. In this manner, we can define a function \text{concat}\{\alpha\} of type list ?a > list ?a > list ?a. With this definition we can use all instances, where we substitute ?a for any other type. For example when we use this function for lists of numbers, we would use the instance \text{concat}\{\text{nat}\}: \text{list nat} > \text{list nat} > \text{list nat}.
Appendix B

Proof systems

B.1 The sequent calculus LK

In GAPT, a sequent is a pair of lists, more precisely of Scala Vectors. The rules of LK are listed below. Proof trees are constructed top-down, starting with axioms and with each rule introducing new inferences. With the exception of the conversion rules, Skolem rules, proof links, and induction rules, the constructors of the rules only allow inferences that are actually valid. Note that the rules are presented here as if they always act on the outermost formulas in the upper sequent, but this is only for convenience of presentation. The rules may operate on any formula in the sequent. The basic constructors actually require the user to specify on which concrete formulas the inference should be performed.

Apart from those basic constructors, there is also a multitude of convenience constructors that facilitate easier proof construction. Moreover, there are so-called macro rules that reduce several inferences to a single command (e.g. introducing quantifier blocks). See the API documentation of the individual rules for details.

**Axioms**

\[
\frac{A \vdash A}{\top \vdash \top} \text{ (Logical axiom)} \quad \frac{\top \vdash \top}{\bot \vdash \bot} \text{ (Reflexivity axiom)}
\]

\[
\frac{}{\vdash \top} \text{ axiom} \quad \frac{}{\bot \vdash \bot} \text{ axiom}
\]

\[
\frac{(t)}{\Gamma \vdash \Delta} \text{ Proof link}
\]

**Cut**

\[
\frac{\Gamma \vdash \Delta, A \quad A, \Sigma \vdash \Pi}{\Gamma, \Sigma \vdash \Delta, \Pi} \text{ (cut)}
\]
Structural rules

Left rules

\[ \frac{\Gamma \vdash \Delta}{A, \Gamma \vdash \Delta} \quad (w:l) \]
\[ \frac{A, A, \Gamma \vdash \Delta}{A, \Gamma \vdash \Delta} \quad (c:l) \]

Right rules

\[ \frac{\Gamma \vdash \Delta}{\Gamma \vdash \Delta, A} \quad (w:r) \]
\[ \frac{\Gamma \vdash \Delta, A, A}{\Gamma \vdash \Delta, A} \quad (c:r) \]

Propositional rules

Left rules

\[ \frac{A, B, \Gamma \vdash \Delta}{A \wedge B, \Gamma \vdash \Delta} \quad (\wedge:l) \]
\[ \frac{A, \Gamma \vdash \Delta}{A \vee B, \Gamma, B, \Sigma \vdash \Pi} \quad (\vee:l) \]
\[ \frac{\Gamma \vdash \Delta, A}{\neg A, \Gamma \vdash \Delta} \quad (\neg:l) \]
\[ \frac{\Gamma \vdash \Delta, A}{A \rightarrow B, \Gamma, B, \Sigma \vdash \Pi} \quad (\rightarrow:l) \]

Right rules

\[ \frac{\Gamma \vdash \Delta, A}{\Gamma, \Sigma \vdash \Delta, \Pi, A \wedge B} \quad (\wedge:r) \]
\[ \frac{\Gamma \vdash \Delta, A, B}{\Gamma \vdash \Delta, A \vee B} \quad (\vee:r) \]
\[ \frac{A, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, \neg A} \quad (\neg:r) \]
\[ \frac{A, \Gamma \vdash \Delta, B}{\Gamma \vdash \Delta, A \rightarrow B} \quad (\rightarrow:r) \]

Quantifier rules

Left rules

\[ \frac{A[x/t], \Gamma \vdash \Delta}{\forall x A, \Gamma \vdash \Delta} \quad (\forall:l) \]
\[ \frac{A[x/y], \Gamma \vdash \Delta}{\exists x A, \Gamma \vdash \Delta} \quad (\exists:l) \]
\[ \frac{A[x/s], \Gamma \vdash \Delta}{\exists x A, \Gamma \vdash \Delta} \quad (\existssk:l) \]

Right rules

\[ \frac{\Gamma \vdash \Delta, A[x/t]}{\Gamma \vdash \Delta, \exists x A} \quad (\exists:r) \]
\[ \frac{\Gamma \vdash \Delta, A[x/y]}{\Gamma \vdash \Delta, \forall x A} \quad (\forall:r) \]
\[ \frac{\Gamma \vdash \Delta, A[x/s]}{\Gamma \vdash \Delta, \forall x A} \quad (\forallsk:r) \]

The variable \( y \) must not occur free in \( \Gamma, \Delta \) or \( A \).

Equality rules
Left rules

\[
s = t, A[x\backslash s], \Sigma \vdash \Pi \quad (=:l)
\]

\[
s = t, A[x\backslash t], \Sigma \vdash \Pi \quad (=:l)
\]

Right rules

\[
s = t, \Sigma \vdash \Pi, A[x\backslash t] \quad (=:r)
\]

\[
s = t, \Sigma \vdash \Pi, A[x\backslash s] \quad (=:r)
\]

Conversion rules

\[
\frac{A, \Gamma \vdash \Delta}{B, \Gamma \vdash \Delta} \quad (\text{conv:l}) \quad \frac{\Gamma \vdash \Delta, A}{\Gamma \vdash \Delta, B} \quad (\text{conv:r})
\]

These conversion rules are extremely liberal, as they allow the replacement of any formula by any other formula. When checking these rules against a context, we verify that both \( A \) and \( B \) normalize to the same normal form.

Induction

The induction rule applies to arbitrary algebraic data types. Let \( c_1, \ldots, c_n \) be the constructors of a type and let \( k_i \) be the arity of \( c_i \). Let \( F[x] \) be a formula with \( x \) a free variable. Then we call the sequent \( S_i := F[x_1], \ldots, F[x_{k_i}], \Gamma_i \vdash \Delta_i, F[c_i(x_1, \ldots, x_{k_i})] \) the \( i \)-th induction step. The induction rule then has the form

\[
\frac{(\pi_1) \quad (\pi_2) \quad \ldots \quad (\pi_n)}{\Gamma \vdash \Delta, F[t]} \quad (\text{ind})
\]

In the case of the natural numbers, there are two constructors: \( 0 \) of arity 0 and \( s \) of arity 1. Consequently, the induction rule reduces to

\[
\frac{\Gamma_1 \vdash \Delta_1, F[0] \quad F[x], \Gamma_2 \vdash \Delta_2, F[sx]}{\Gamma_1, \Gamma_2 \vdash \Delta_1, \Delta_2, F[t]} \quad (\text{ind})
\]

B.2 Natural Deduction ND

The rules of ND are listed below. Classical logic is supported by providing the excluded middle rule. We use ND rules in sequent form. An NDSequent has exactly one formula on the right.

As in LK, proof trees are constructed top-down, starting with axioms and with each rule introducing new inferences. With exception of the proof links and the induction rules, the constructors of the rules only allow inferences that are actually valid. Note that the rules are presented here as if they
always act upon the outermost formulas in the upper sequent, but this is only for convenience of presentation. The basic constructors actually require the user to specify on which concrete formulas the inference should be performed.

Apart from those basic constructors, there is also a multitude of convenience constructors that facilitate easier proof construction. See the API documentation of the individual rules for details.

### Axioms

\[ A \vdash A \quad \text{(Logical axiom)} \]

\[ \vdash A \quad \text{(Theory axiom)} \]

### Structural rules

\[ \Gamma \vdash B \quad \text{(w)} \]

\[ A, \Gamma \vdash B \quad \text{(c)} \]

### Propositional rules

#### Elimination rules

\[ \Gamma \vdash A \land B \quad \text{\(\land\):e1} \]

\[ \frac{\Gamma \vdash A \land B}{\Gamma \vdash A} \quad \text{(\(\land\):i)} \]

\[ \frac{\Gamma \vdash A \land B}{\Gamma \vdash B} \quad \text{(\(\land\):e2)} \]

\[ \frac{\Gamma \vdash A \lor B \quad \Pi, A \vdash C \quad \Delta, B \vdash C}{\Gamma, \Pi, \Delta \vdash C} \quad \text{(\(\lor\):e)} \]

\[ \frac{\Gamma \vdash \neg A \quad \Pi \vdash A}{\Gamma, \Pi \vdash \bot} \quad \text{(\(\neg\):e)} \]

\[ \frac{\Gamma \vdash A \rightarrow B \quad \Pi \vdash A}{\Gamma, \Pi \vdash B} \quad \text{(\(\rightarrow\):e)} \]

\[ \frac{\Gamma \vdash \bot}{\Gamma \vdash A} \quad \text{(\(\bot\):e)} \]

#### Introduction rules

\[ \frac{\Gamma \vdash A \quad \Pi \vdash B}{\Gamma \vdash A \land B} \quad \text{(\(\land\):i)} \]

\[ \frac{\Gamma \vdash A \quad \Pi \vdash B}{\Gamma \vdash A \lor B} \quad \text{(\(\lor\):i1)} \]

\[ \frac{\Gamma \vdash A \quad \Pi \vdash A}{\Delta \vdash A} \quad \text{(\(\lor\):i2)} \]

\[ \frac{A, \Gamma \vdash \bot}{\Gamma \vdash \neg A} \quad \text{(\(\neg\):i)} \]

\[ \frac{A, \Gamma \vdash B}{\Gamma \vdash A \rightarrow B} \quad \text{(\(\rightarrow\):i)} \]

\[ \frac{\Gamma \vdash \bot}{\Gamma \vdash \top} \quad \text{\(\top\):i} \]

### Quantifier rules

#### Elimination rules

\[ \Gamma \vdash \forall x A \quad \Pi, A[x/y] \vdash B \quad \text{\((\forall\):e)} \]

\[ \frac{\Gamma \vdash \exists x A \quad \Pi, A[x/y] \vdash B}{\Gamma, \Pi \vdash B} \quad \text{\((\exists\):e)} \]
Introduction rules

\[ \begin{align*}
\Gamma \vdash A[x \backslash y] & \quad \Gamma \vdash \forall x A \\
\Gamma \vdash A[\Gamma, x \backslash t] & \quad \Gamma \vdash \exists x A
\end{align*} \]

The variable \( y \) must not occur free in \( \Gamma, A \) in case of \( \forall \) introduction, and must not occur free in \( \Pi, A, B \) in case of \( \exists \) elimination.

Equality rules

Elimination rules

\[ \Gamma \vdash s = t \quad \Pi \vdash A[s/x] \quad \Rightarrow \quad \Pi, \Pi \vdash A[t/x] \]

Introduction rules

\[ \vdash t = t \]

Definition rule

\[ \begin{align*}
\Gamma \vdash A & \quad \Gamma \vdash B \\
\Gamma \vdash A \quad \Gamma \vdash B
\end{align*} \]

The definition rule is extremely liberal, as it allows the replacement of any formula by any other formula. When checking this rule against a context, we verify that both \( A \) and \( B \) normalize to the same normal form.

Induction

The induction rule applies to arbitrary algebraic data types. Let \( c_1, \ldots, c_n \) be the constructors of a type and let \( k_i \) be the arity of \( c_i \). Let \( F[x] \) be a formula with \( x \) a free variable of the appropriate type. Then we call the sequent \( S_i := F[x_1], \ldots, F[x_{k_i}], \Gamma_i \vdash F[c_i(x_1, \ldots, x_{k_i})] \) the \( i \)-th induction step. The induction rule then has the form

\[ \begin{align*}
\pi_1 & \quad \pi_2 & \quad \ldots & \quad \pi_n \\
S_1 & \quad S_2 & \quad \ldots & \quad S_n
\end{align*} \]

\( \Gamma \vdash F[t] \)

\( \text{ind} \)

In the case of the natural numbers, there are two constructors: \( 0 \) of arity 0 and \( s \) of arity 1. Consequently, the induction rule reduces to

\[ \begin{align*}
\pi_1 & \quad \pi_2 \\
\Gamma_1 \vdash F[0] & \quad F[x], \Gamma_2 \vdash F[sx]
\end{align*} \]

\( \text{ind} \)

Excluded Middle

\[ \begin{align*}
\Gamma, A \vdash B & \quad \Pi, \neg A \vdash B \\
\Gamma, \Pi \vdash B
\end{align*} \]

\( \text{em} \)
B.3 Resolution

Our resolution calculus integrates higher-order reasoning, structural clausification, and Avatar-style splitting as in [17]. The judgments of this calculus are A-sequents. An A-sequent \( S \rightarrow A \) is a pair of a sequent \( S \) of HOL formulas, and a conjunction \( A \) of propositional literals:

\[
\Gamma \vdash \Delta \rightarrow A
\]

Internally, we represent the (negation of the) assertion as a clause. The judgment \( \Gamma \vdash \Delta \rightarrow A \) is interpreted as the following formula, where \( \mathcal{F} \) are the free variables of the sequent:

\[
A \rightarrow \forall \mathcal{F} \left( \bigwedge \Gamma \rightarrow \bigvee \Delta \right)
\]

Inferences such as resolution or paramodulation do not operate on the assertions. Unless specified otherwise, assertions are inherited by default, combined with a conjunction:

\[
\Gamma, \Pi \vdash \Delta, \Lambda \rightarrow A \land B
\]

Resolution

There is no factoring on assertions, duplicate assertions are automatically removed. Substitutions are not absorbed into resolution, factoring, and paramodulation; they are explicitly represented using the Subst inference.

**Initial sequents**

- **Input**
  \[
  S \]

- **Refl**
  \[
  t = t
  \]

- **Taut**
  \[
  a \vdash a
  \]

- **Defn**
  \[
  \vdash \forall x (D(x) \equiv \varphi(x))
  \]

**Structural rules**

- **Factor**
  \[
  a, a, \Gamma \vdash \Delta \Rightarrow a, \Gamma \vdash \Delta
  \]

- **Factor**
  \[
  \Gamma \vdash \Delta, a, a \Rightarrow \Gamma \vdash \Delta, a
  \]

- **Subst**
  \[
  S \sigma \Rightarrow S
  \]
Logical rules

\[
\frac{\Gamma \vdash \Delta, a \quad \Pi \vdash \Lambda}{\Gamma, \Pi \vdash \Delta, \Lambda} \quad \text{Resolution}
\]

\[
\frac{\Gamma \vdash \Delta, t = s \quad \Pi \vdash \Lambda, a[t]}{\Gamma, \Pi \vdash \Delta, \Lambda, a[s]} \quad \text{Paramod}
\]

(We also allow rewriting in the antecedent, and rewriting from right to left.)

\[
\frac{\Gamma \vdash \Delta, t = s}{\Gamma \vdash \Delta, s = t} \quad \text{Flip}
\]

\[
\frac{t = s, \Gamma \vdash \Delta}{s = t, \Gamma \vdash \Delta} \quad \text{Flip}
\]

Propositional rules

\[
\frac{\top, \Gamma \vdash \Delta}{\Gamma \vdash \Delta} \quad \text{TopL}
\]

\[
\frac{\Gamma \vdash \Delta, \bot}{\Gamma \vdash \Delta} \quad \text{BottomR}
\]

\[
\frac{\neg a, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, a} \quad \text{NegL}
\]

\[
\frac{a, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, a} \quad \text{NegR}
\]

\[
\frac{a \land b, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, a \land b} \quad \text{AndL}
\]

\[
\frac{a \land b, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, a} \quad \text{AndR1}
\]

\[
\frac{a \land b, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, b} \quad \text{AndR2}
\]

\[
\frac{a \lor b, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, a \lor b} \quad \text{OrL1}
\]

\[
\frac{a \lor b, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, a} \quad \text{OrL2}
\]

\[
\frac{a \lor b, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, b} \quad \text{OrR}
\]

\[
\frac{a \Rightarrow b, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, a \Rightarrow b} \quad \text{ImpL1}
\]

\[
\frac{a \Rightarrow b, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, a} \quad \text{ImpL2}
\]

\[
\frac{a \Rightarrow b, \Gamma \vdash \Delta}{\Gamma \vdash \Delta, b} \quad \text{ImpR}
\]

\[
\frac{\forall x \varphi(x), \Gamma \vdash \Delta}{\varphi(s(...)), \Gamma \vdash \Delta} \quad \text{AllL}
\]

\[
\frac{\exists x \varphi(x), \Gamma \vdash \Delta}{\varphi(x), \Gamma \vdash \Delta} \quad \text{ExL}
\]

\[
\frac{\varphi(\pi), \Gamma \vdash \Delta}{D(\pi), \Gamma \vdash \Delta} \quad \text{DefIntro}
\]

Avatar rules

By \([C]\) we denote the propositional atom representing the clause component \(C\).

\[
\frac{C, S \leftarrow A}{S \leftarrow A \land \neg[C]} \quad \text{AvatarSplit}
\]

(For simplicity, the AvatarSplit rule only splits away a single clause component at a time.)

\[
\frac{C \leftarrow [C]}{\Gamma \vdash \Delta \leftarrow a_1 \land a_2 \land \cdots \land b_1 \land \neg b_2 \land \cdots} \quad \text{AvatarComponent}
\]

\[
\frac{a_1, a_2, \ldots, \Gamma \vdash \Delta, b_1, b_2, \ldots}{\Gamma \vdash \Delta} \quad \text{AvatarContradiction}
\]
B.4 Expansion trees

Expansion trees are a compact representation of quantifier inferences in proofs with cuts. They have originally been introduced in [14]. GAPT contains an extension by Skolem nodes, weakening nodes, definitions, merges, and cuts [13].

- **ETAtom** \( A \) (where \( A \) is a HOL atom)
- **ETWeakening** \( \text{wk}(\varphi) \) (where \( \varphi \) is a formula)
- **ETMerge** \( E_1 \sqcup E_2 \)
- **ETDefinition** \( D +_{\text{def}} E \) (where \( D \) is definitionally equal to the shallow formula of \( E \))
- **ETTop** \( \top \)
- **ETBottom** \( \bot \)
- **ETNeg** \( \neg E \)
- **ETAnd** \( E_1 \land E_2 \)
- **ETOr** \( E_1 \lor E_2 \)
- **ETImp** \( E_1 \rightarrow E_2 \)
- **ETWeakQuantifier** \( Qx\varphi +_{t_1} \varphi[x/t_1] \cdots +_{t_n} \varphi[x/t_n] \) (where \( Q \) is a quantifier and \( t_i \) terms)
- **ETStrongQuantifier** \( Qx\varphi +_{\text{ev}} \varphi[x/\alpha] \) (where \( Q \) is a quantifier and \( \alpha \) an eigenvariable)
- **ETSkolemQuantifier** \( Qx\varphi +_{sk} \varphi[x/s] \) (where \( Q \) is a quantifier and \( s \) a Skolem term)

Cuts are represented as expansions of the cut axiom \( \forall X \ (X \rightarrow X) \) in the antecedent.
